8 Appendix and Supplementary Information

8.1 A Formal Insurance Model of Redistribution Preferences

This appendix states the model behind Section 2.4 and gives the exact expressions for its comparative statics. The propositions are proved analytically and verified symbolically, and the closing remark records which sign regions were mapped numerically.

Primitives. An individual has pre-tax income y; mean income is $\bar{y}$, and relative income is $\xi \equiv y/\bar{y}$. With probability p she is displaced; with probability $1-p$ she keeps her job and earns y. Displacement is a temporary spell. Let $\mu \in [0,1]$ be the expected share of the period spent unemployed, $\rho \in [0,1]$ the re-entry wage ratio (so $1-\rho$ is scarring), b the earnings-related benefit replacement rate, and B the benefit duration as a share of the period. Income in the bad state is δy, with

$$\delta \;=\; (1-\mu)\,\rho \;+\; b \cdot \min(\mu, B). \tag{6}$$

δ is a derived quantity with four separately observable components; it is not a free parameter summarizing protection. Interpretation depends on the distinction: each institution enters through the component on which it acts.

Policy. A linear tax $\tau \in [0,1]$ on income funds transfers that accrue at rate θ_g in the good state and θ_b in the bad state, with $\theta_b \geq \theta_g \geq 0$. Income proportionality separates δ from θ: δ collects payments that scale with the individual's own prior earnings and are exogenous to her policy choice, while θ collects flat payments that scale with the chosen tax rate. Earnings-related unemployment insurance therefore belongs in δ; flat-rate benefits and social assistance belong in θ_b. Consumption is affine in τ:

$$c_g \;=\; \xi - \tau(\xi - \theta_g), \qquad c_b \;=\; \delta\xi + \tau(\theta_b - \delta\xi). \tag{7}$$

Preferences and objective. Utility is CRRA, $u(c) = c^{1-\sigma}/(1-\sigma)$ for $\sigma > 0$, with $u(c) = \ln c$ at $\sigma = 1$. The individual maximizes

$$V(\tau) \;=\; (1-p)\,u(c_g) \;+\; p\,u(c_b). \tag{8}$$

CRRA is homothetic, so only relative income matters; we set $\bar{y} = 1$. This matches the measurement practice in the empirical sections, where the income control is equivalized income relative to the country-year mean.

Interior region. Assume

$$\delta\xi \;<\; \theta_b, \qquad \theta_g \;<\; \xi. \tag{9}$$

The second inequality makes the individual a net contributor when employed; the first makes her a net recipient when displaced. Together they generate an insurance trade-off; outside this region the problem has a corner solution.

Solution and comparative statics. Write $A \equiv \xi - \theta_g$, $C \equiv \theta_b - \delta\xi$, $G \equiv \theta_b - \delta\theta_g$, and $D \equiv A + \kappa C$.

Proposition 1 (Optimal tax rate)**.** *Under* (9)*, V is strictly concave in τ and the optimum is*

$$\tau^* \;=\; \frac{\xi\,(1-\kappa\delta)}{D}, \qquad \kappa \;\equiv\; \left[\frac{(1-p)\,A}{p\,C}\right]^{1/\sigma}, \tag{10}$$

interior whenever $\kappa\delta < 1$ and $\tau^* < 1$.

Proof. The first-order condition $V'(\tau) = 0$ gives $(c_g/c_b)^\sigma = (1-p)A/(pC)$, so $c_g = \kappa c_b$. $V''(\tau) = -\sigma(1-p)A^2 c_g^{-\sigma-1} - \sigma p C^2 c_b^{-\sigma-1} < 0$, so the critical point is the global maximum. Substituting (7) into $c_g = \kappa c_b$ and solving for τ yields (10). □

The auxiliary variable $\kappa = c_g/c_b \geq 1$ is the risk the individual still bears at her chosen policy; each comparative static below depends on it. The risk slope, the model analogue of the estimated

slopes β_{ct}, also has a closed form:

$$\beta \;\equiv\; \frac{\partial \tau^*}{\partial p} \;=\; \frac{\xi\, G\, \kappa}{\sigma\, p\,(1-p)\, D^2}. \tag{11}$$

Proposition 2 (Risk raises demand unconditionally). *If $\theta_b > \delta\theta_g$, then $\partial\tau^*/\partial p > 0$ throughout the interior region, for every $\sigma > 0$ and $\delta \in [0, 1)$.*

Proof. $\partial\tau^*/\partial\kappa = -\xi G/D^2 < 0$ and $d\kappa/dp = -\kappa/[\sigma p(1-p)] < 0$; the product is (11), which is positive. □

The condition $\theta_b > \delta\theta_g$ is implied by $\theta_b \geq \theta_g$ and $\delta < 1$, so it does not bind in any case of interest. This is the model's only unconditional prediction, and it requires no restriction on risk aversion.

Proposition 3 (The risk slope declines in baseline risk). *With $r \equiv A/(\kappa C)$,*

$$\text{sign}\left(\frac{\partial \beta}{\partial p}\right) \;=\; \text{sign}\left\{(2p-1) \;+\; \frac{1-r}{\sigma(1+r)}\right\}. \tag{12}$$

Sufficient for a negative sign: $p \leq 1/2$ and $r \geq 1$.

Proposition 4 (The curvature effect vanishes at log utility). *At $\sigma = 1$, $r = p/(1-p)$ and the bracket in Proposition 3 is identically zero, so $\partial\beta/\partial p = 0$ for every interior p.*

Proof. At $\sigma = 1, \kappa = (1-p)A/(pC)$, so $r = A/(\kappa C) = p/(1-p)$. Then $1-r = (1-2p)/(1-p)$ and $1+r = 1/(1-p)$, so $(1-r)/(1+r) = 1-2p$ and the bracket is $(2p-1)+(1-2p) = 0$. □

The two sufficient conditions therefore cannot both hold at log utility. For $p < 1/2$ the first holds and the second fails exactly, because $r = p/(1-p) < 1$. The curvature channel is a second-order effect that requires curvature in the utility function beyond the logarithmic case, and it strengthens as σ rises above one. At empirically relevant displacement probabilities and $\sigma > 1$ the slope is steepest where baseline risk is lowest, which is a channel distinct from the composition of the bad state, because an institution that lowers the level of displacement risk steepens the exposure gradient without changing what a displaced worker retains. Since the meta-analytic estimates invoked for Proposition 5 place σ near one, the model predicts no

curvature effect at the calibration this paper adopts, and employment protection therefore carries no signed prediction there.

Proposition 5 (The income effect is not signed)**.**

$$\frac{d\tau^*}{d\xi} \;=\; \frac{(\kappa\theta_b - \theta_g)(1-\kappa\delta) \;-\; \xi G\kappa'_\xi}{D^2}, \qquad \kappa'_\xi \;=\; \frac{\kappa}{\sigma}\left(\frac{1}{A}+\frac{\delta}{C}\right). \tag{13}$$

The two terms oppose each other, and the balance depends on σ. As $\sigma \to \infty$, κ'_ξ vanishes and the effect is positive: insurance behaves as a normal good, the region of Moene and Wallerstein (2001). At low σ the second term dominates and the effect is negative, the benchmark of Meltzer and Richard (1981). Under full targeting ($\theta_g = 0$) with log utility, income drops out of (10) *entirely, the knife-edge of Alt and Iversen (2017).*

Proposition 6 (The income-by-risk interaction is not generic)**.**

$$\frac{\partial \ln \beta}{\partial \xi} \;=\; \frac{1}{\xi} \;+\; \frac{\kappa'_\xi}{\kappa} \;-\; \frac{2\,(1-\kappa\delta+\kappa'_\xi C)}{D}. \tag{14}$$

The sign is a joint restriction on risk aversion, loss severity, and transfer targeting. Positive signs concentrate at σ near two or above with δ bounded away from zero, or under narrow targeting.

Proposition 7 (Transfers and retention move the slope in opposite directions)**.**

$$\frac{\partial \ln \beta}{\partial \theta_b} \;=\; \frac{1}{G} - \frac{1}{\sigma C} - \frac{2\kappa\,(1-1/\sigma)}{D}, \qquad \frac{\partial \ln \beta}{\partial \delta} \;=\; -\frac{\theta_g}{G} + \frac{\xi}{\sigma C} + \frac{2\kappa\xi\,(1-1/\sigma)}{D}. \tag{15}$$

The derivatives in Proposition 7 are not signed globally, but they admit an exact decomposition that yields analytic sufficient conditions and links the two signs.

Proposition 8 (Sufficient conditions for the transfer and retention signs)**.** *With $r \equiv A/(\kappa C)$ as in Proposition 3,*

$$\frac{\partial \ln \beta}{\partial \theta_b} \;=\; -\frac{\delta A}{GC} \;+\; \frac{(\sigma-1)(r-1)}{\sigma}\,\frac{\kappa}{D}, \qquad \frac{\partial \ln \beta}{\partial \delta} \;=\; \frac{\theta_b A}{GC} \;-\; \frac{(\sigma-1)(r-1)}{\sigma}\,\frac{\xi\kappa}{D}, \tag{16}$$

and the two derivatives satisfy the identity

$$\xi \frac{\partial \ln \beta}{\partial \theta_b} + \frac{\partial \ln \beta}{\partial \delta} = \frac{A}{G} > 0. \tag{17}$$

Consequently, whenever $(\sigma - 1)(r - 1) \leq 0$*, raising the flat transfer weakly lowers the risk slope, strictly when* $\delta > 0$*, and raising the retention share strictly raises it; at* $\sigma = 1$ *both signs hold unconditionally, with* $\partial \ln \beta / \partial \theta_b = -\delta A/(GC)$ *and* $\partial \ln \beta / \partial \delta = \theta_b A/(GC)$ *exactly. By* (17)*, whenever the transfer derivative is negative the retention derivative exceeds* $A/G > 0$*, so the two routes cannot both take the opposite of their predicted signs. In primitives,* $r \lessgtr 1$ *is equivalent to* $(A/C)^{\sigma-1} \lessgtr (1-p)/p$*; in particular* $A \leq C$ *and* $p \leq 1/2$ *imply* $r \leq 1$ *for every* $\sigma \geq 1$*.*

Proof. From Proposition 7, $1/G - 1/C = (C - G)/(GC) = -\delta A/(GC)$ and $\xi/C - \theta_g/G = \theta_b A/(GC)$, while $1/C - 2\kappa/D = (A - \kappa C)/(CD) = \kappa(r-1)/D$; substituting gives (16), and (17) follows by direct addition since $\xi\, \delta A/(GC)$ cancels against $\theta_b A/(GC)$ minus $AC/(GC)$. The sign statements read off the decomposition: the first terms carry the stated signs on the interior region, and the correction terms share the factor $(\sigma - 1)(r - 1)$ with opposite signs. The primitive form follows from $r = (A/C)^{1-1/\sigma} [(1-p)/p]^{-1/\sigma}$. All three identities were verified symbolically. □

The condition reads directly: r compares the proportional consumption stakes of taxation across the two states, and $(\sigma - 1)(r - 1) \leq 0$ requires risk aversion and the stake ratio to sit on opposite sides of one. Meta-analytic estimates place σ near one (Elminejad et al., 2022), where the signs need no condition at all. Outside the sufficient region the transfer derivative can reverse, and on the appendix grids the reversals are confined to that region and concentrate at small δ, and by (17) a reversal of the retention derivative also requires $\xi\, \partial \ln \beta / \partial \theta_b > A/G$, which occurs on under one percent of interior draws.

The last result is both a prediction and an identification warning: the same unemployment-insurance policy buffers the exposure gradient if written as a transfer and amplifies it if written as retained income. Institutions must therefore be mapped through the primitives in (6), because policy labels do not determine the sign. Unions and bargaining coverage act on several primitives at once (ρ, the separation rate, and θ_b) and are left unsigned. Benefit duration B is

also unsigned once its behavioral effect on μ is allowed to vary over the range documented in quasi-experimental work, and the re-entry wage ratio ρ has no country-year series, which leaves three of the five primitives signed and two unsigned.

Remark 1. The expressions above are exact and were verified symbolically (`sympy`); the closed form (10) was checked against direct numerical maximization of (8) on 2,533 interior draws with no discrepancy above 10^{-5}. The sign regions reported for Propositions 3 through 6 were mapped numerically over interior draws spanning $\xi \in [0.3, 3]$, $p \in [0.02, 0.5]$, $\delta \in [0, 0.8]$, $\sigma \in [0.4, 4]$, $\theta_g \in [0, 1]$, and $\theta_b \in [\theta_g, 2]$; the verification code accompanies the replication materials.

Nested cases. As $p \to 0$ the insurance motive vanishes and only the redistributive motive survives (Meltzer and Richard, 1981). Setting $\theta_g = 0$, $\delta = 0$, $\sigma = 1$ collapses (10) to $\tau^* = p$, the result of Alt and Iversen (2017): the preferred tax rate equals the probability of falling into poverty, independent of own income. Setting $\theta_g = \gamma$, $\theta_b = 1 - \gamma$, $\delta = 0$, $\sigma = 1$ gives $\tau^* = p\,\xi/(\xi - \gamma)$, the closed form of Pahontu (2022). High σ with $\delta \approx 0$ yields $d\tau^*/d\xi > 0$, the region of Moene and Wallerstein (2001). As the main text notes, after correction for publication bias the meta-analytic estimates of relative risk aversion center on one (Elminejad et al., 2022). At that value the Moene–Wallerstein region and the positive income-by-risk interaction both lie outside the admissible parameter space.

Mapping to automation exposure. Let a denote occupational automation exposure. With $p = p(a)$, $\xi = \xi(a)$, $\delta = \delta(a)$,

$$\frac{d\tau^*}{da} \;=\; \frac{\partial \tau^*}{\partial p}\,\frac{dp}{da} \;+\; \frac{\partial \tau^*}{\partial \xi}\,\frac{d\xi}{da} \;+\; \frac{\partial \tau^*}{\partial \delta}\,\frac{d\delta}{da}, \tag{18}$$

so an estimated exposure coefficient is a composite of a risk channel, an expected-wage channel, and a severity channel. The model signs only the risk channel. This is one reason the paper does not treat its mechanism analyses as tests.

8.2 Supplementary Figures and Tables

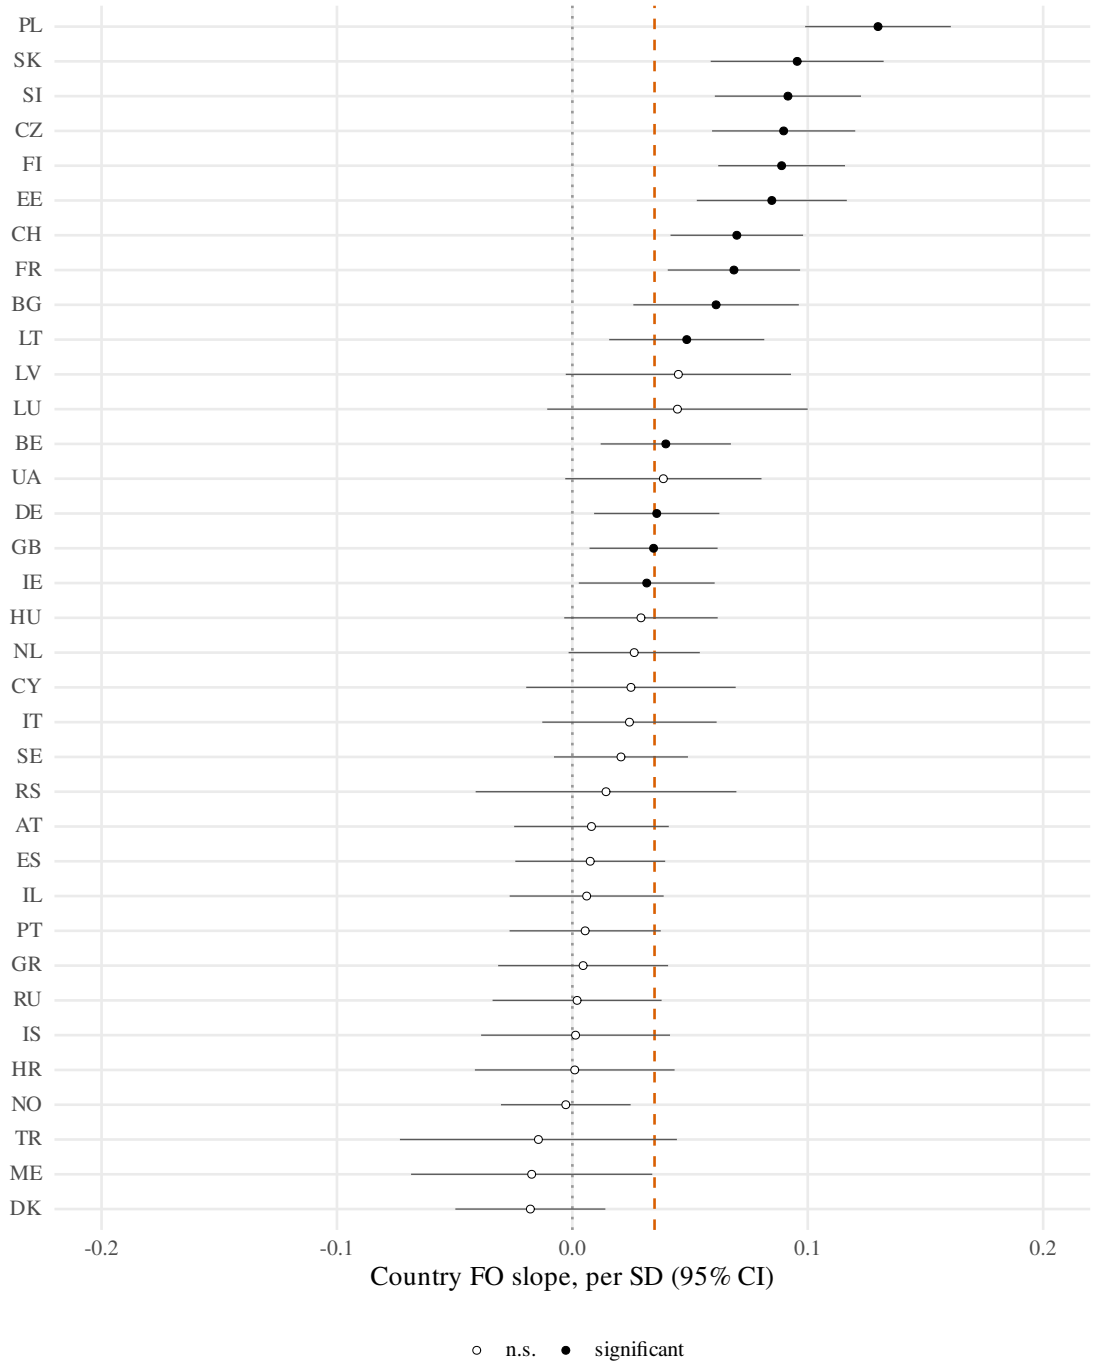

The material in this appendix covers robustness results for RTI, country and year slope profiles, composition aggregates, latest-wave country estimates, mediation diagnostics, a single-wave diagnostic of exposure and perceived vulnerability, and the institutional two-stage diagnostic.

Table 4: Global RTI automation–redistribution association: published benchmark and post-estimation window aggregates of the single heterogeneity model

Quantity	Years	Scale	Estimate	95% CI	N	Countries
Published benchmark	2002–2012	per SD	0.042	–	64,639	17
Window aggregate of $\beta_{c,t}$	2002–2012	native	0.039	[0.021, 0.058]	96,811	33
Window aggregate of $\beta_{c,t}$	2014–2022	native	0.016	[-0.003, 0.035]	83,165	33
Full-panel aggregate of $\beta_{c,t}$	2002–2022	native	0.028	[0.010, 0.046]	179,976	35
Benchmark-roster aggregate	2002–2012	native	0.042	[0.022, 0.061]	65,134	17
Benchmark-roster aggregate	2014–2022	native	0.019	[-0.001, 0.039]	51,216	16
Benchmark-roster aggregate	2002–2022	native	0.032	[0.013, 0.050]	116,350	17
Full-panel aggregate of $\beta_{c,t}$	2002–2022	per SD	0.027	[0.010, 0.043]	179,976	35

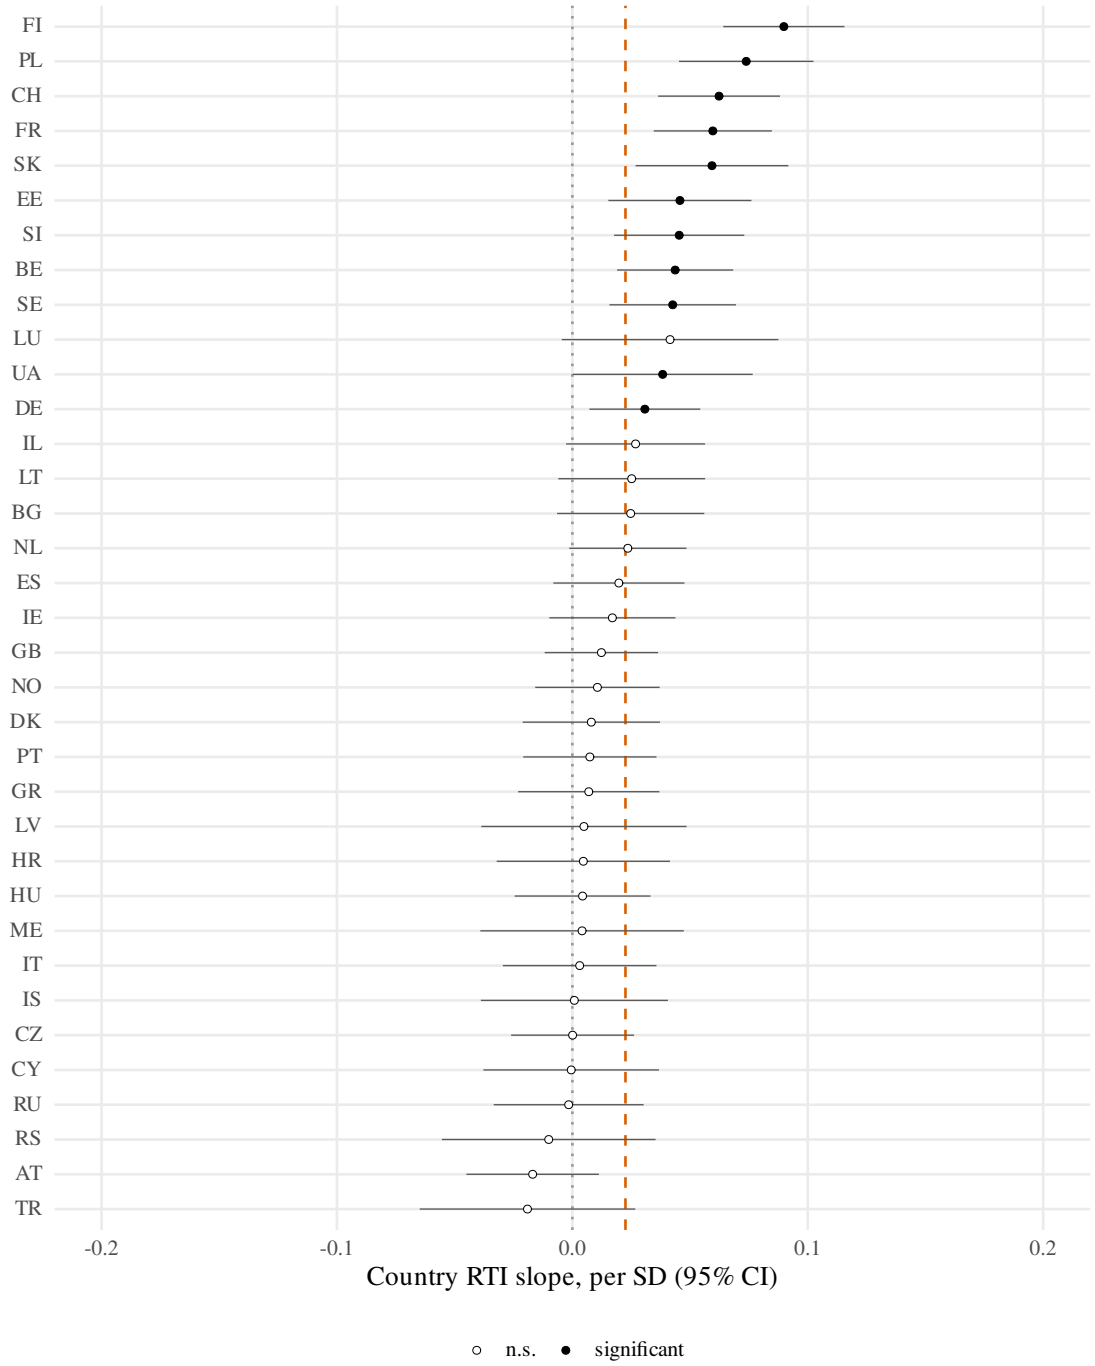

Window aggregates are equal-weighted means of the country-year slopes $\beta_{c,t}$ from the single multilevel heterogeneity model; no additional model is estimated. The model adjusts for relative equivalized household income, years of education, gender, age, union membership, religiosity, and unemployment status, with ESS design weights. Benchmark-roster rows restrict the aggregation to the seventeen countries of the published benchmark's sample, holding country composition fixed at the benchmark roster. Native-scale entries divide the per-SD aggregate by the pooled exposure SD. Intervals carry over the fixed-slope sampling variance and the aggregated conditional variances of the slope components; cross-component posterior covariances are ignored. The published-benchmark row is quoted from Thewissen and Rueda (2019) as an external reference.

Figure 9: Marginal country slopes from the single heterogeneity model, Frey–Osborne

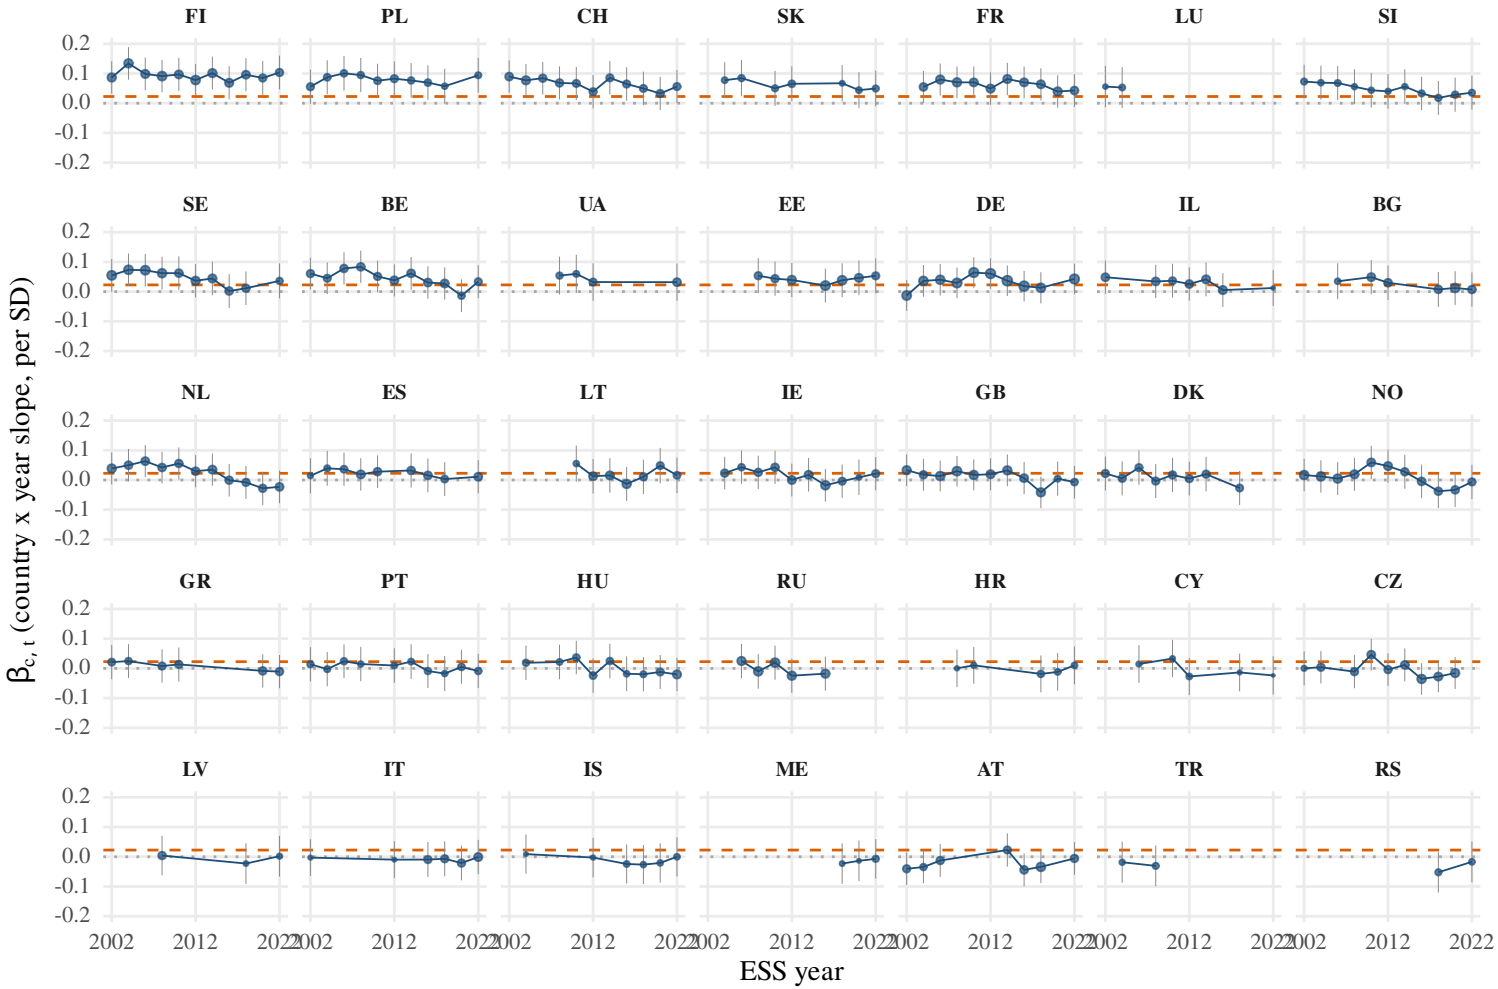

Note: Country slopes are the fitted $\gamma + u_c$ (global slope plus country deviation) from the single model. Dashed orange = global slope; dotted line at zero. Effect axis fixed at $[-0.20, +0.20]$, shared across all slope figures.

Figure 10: Marginal country slopes from the single heterogeneity model, RTI

Note: Country slopes are the fitted $\gamma + u_c$ (global slope plus country deviation) from the single model. Dashed orange = global slope; dotted line at zero. Effect axis fixed at $[-0.20, +0.20]$, shared across all slope figures.

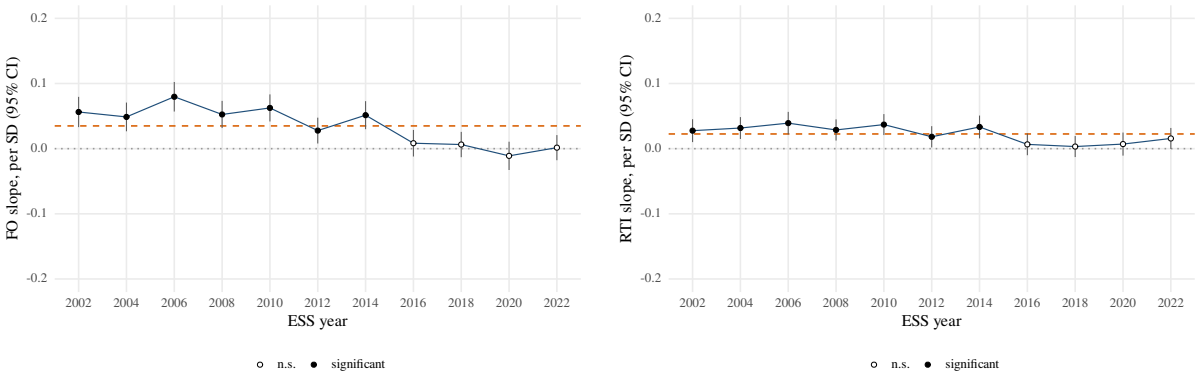

Figure 11: RTI robustness: country-by-year heterogeneity in the automation–redistribution association

Note: Each panel is a country, ordered by mean slope; point size scales with cell N. Dashed orange = global slope; dotted line at zero. Whiskers are 95% intervals from the fitted slope surface, cropped at the panel edge where they exceed the range. Effect axis fixed at $[-0.20, +0.20]$, shared across all slope figures.

Figure 12 plots the fitted year slopes; their between-year standard deviation is 0.030 under Frey–Osborne and 0.015 under RTI.

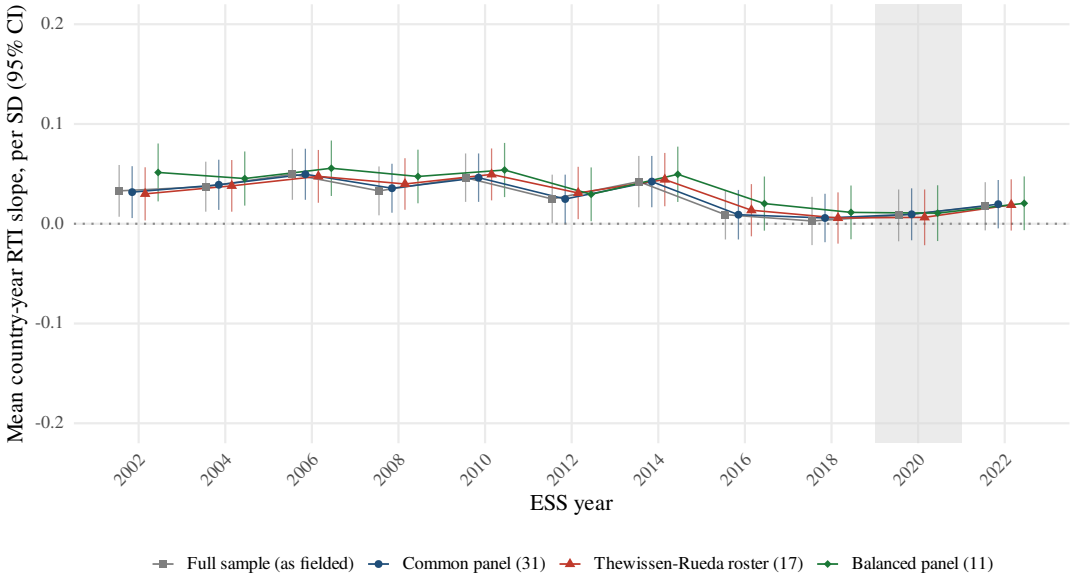

Figure 12: Marginal year slopes from the single heterogeneity model (composition-confounded)

Note: Left panel: Frey–Osborne; right panel: RTI. Points are the fitted $\gamma + v_t$ year slopes from the single model, which are composition-confounded; the composition-controlled aggregates appear in Figures 3 and 13. Dashed orange = global slope; dotted line at zero. Effect axis fixed at $[-0.20, +0.20]$, shared across all slope figures.

Figure 13 gives the RTI counterpart to Figure 3. It aggregates the fitted RTI country-year slopes $\beta_{c,t}$ over the same four rosters and constructs intervals in the same way. The RTI series also differ in level across rosters, decline after 2014, and partly recover in 2022.

Figure 13: RTI robustness: yearly mean country-year slopes under four composition assumptions

Note: Series are offset horizontally to avoid overlap; the shaded band marks the COVID-disrupted 2020 round (ESS10); dotted line at zero. Whiskers are 95% intervals from the fitted slope surface. Effect axis fixed at $[-0.20, +0.20]$, shared across all slope figures.

The membership of each country roster used in the composition analysis appears in Table 5,

together with the number of observed waves per country.

The design-weighted mean of both exposure indices is tracked in Figure 14 by round for the seventeen countries of the benchmark roster, and Figure 15 plots the corresponding design-weighted densities by round, with a common bandwidth per index and the earliest round at the top, and the distributions drift toward lower exposure across rounds. The design-weighted Frey–Osborne mean falls from 0.52 in 2002 to 0.47 in 2022, and the RTI mean falls from -0.04 to -0.20 over the same rounds, so the labor force of the benchmark roster moved away from routine-intensive occupations.

Figure 14: Design-weighted mean exposure by ESS round, benchmark roster

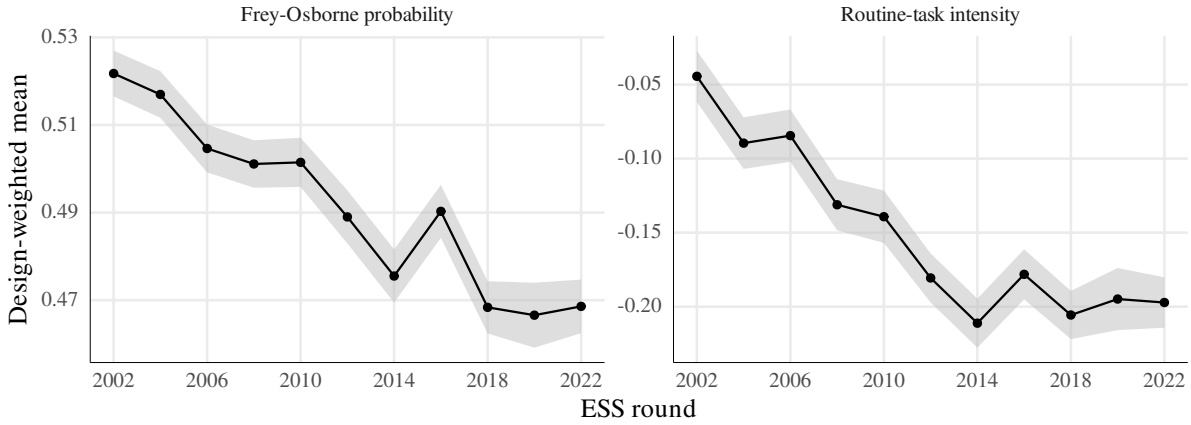

Figure 15: Design-weighted exposure distributions by ESS round, benchmark roster

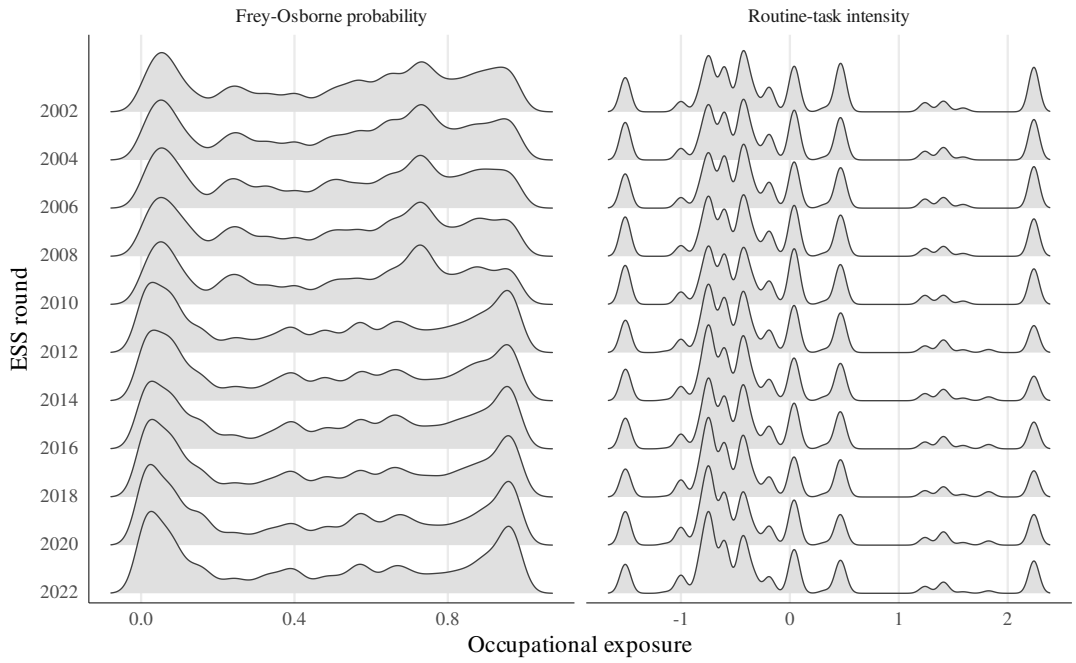

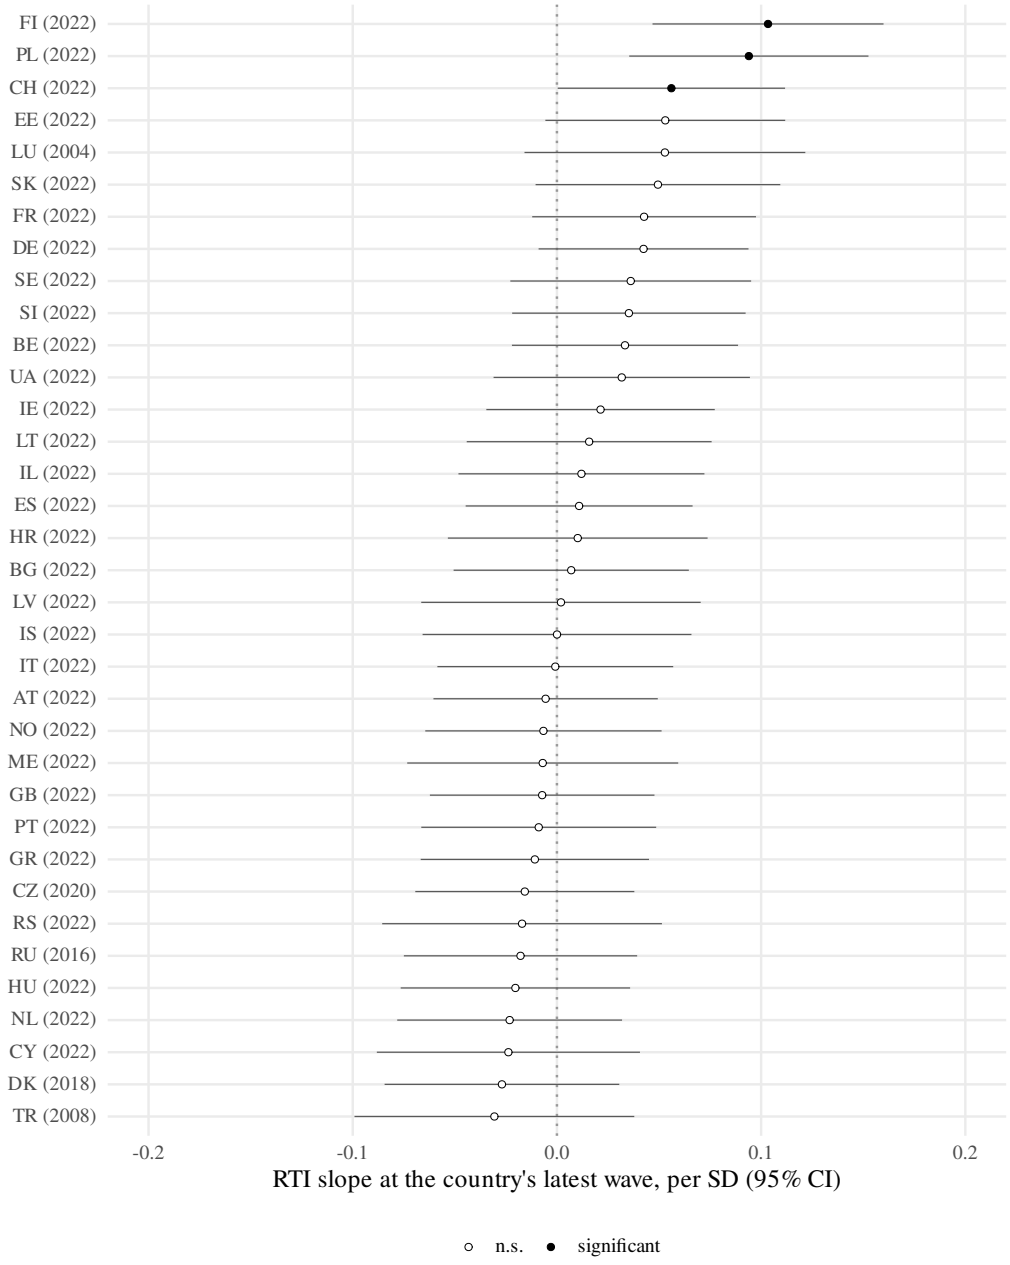

Table 5: Country membership in each analysis roster

Waves counts the ESS rounds in which the country appears in the harmonized 2002–2022 panel (eleven rounds). Full: every country fielded in the panel. Common: at least three waves and at least one pre-2016 wave. TR: the seventeen countries of the Thewissen and Rueda (2019) main sample. Balanced: present in all eleven waves. Roster definitions follow the composition analysis code.

Figure 16: RTI robustness: country marginal effects at the most recent available wave

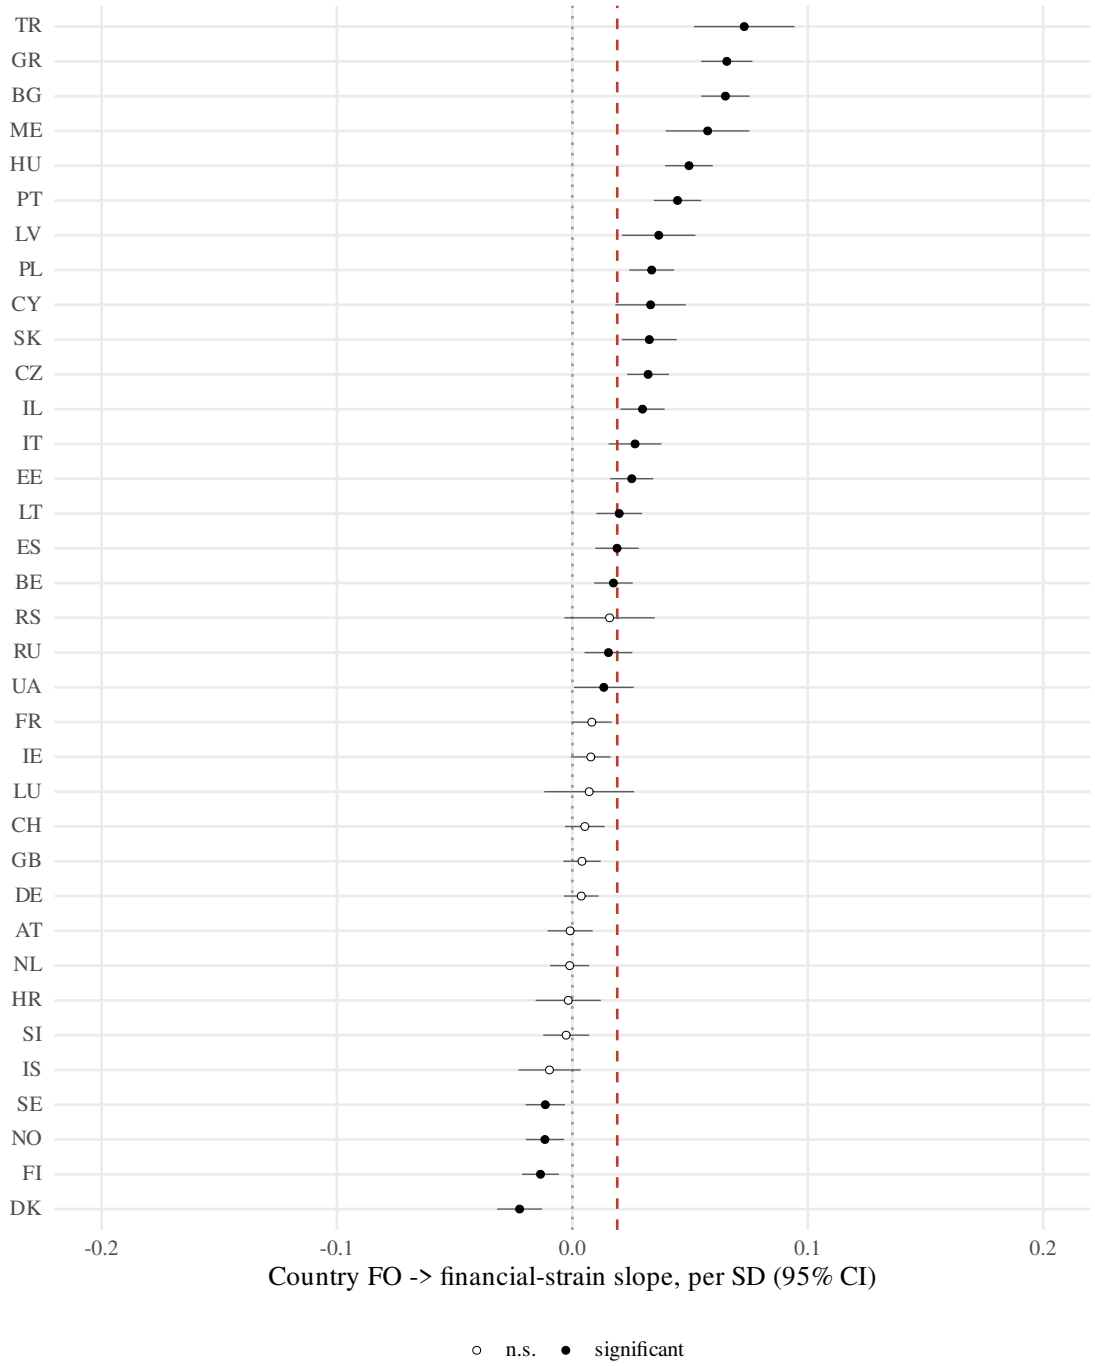

Note: Year in parentheses is each country's most recent ESS round. Whiskers are 95% intervals from the fitted slope surface; dotted line at zero. Effect axis fixed at $[-0.20, +0.20]$, shared across all slope figures.

Figure 17: RTI robustness: country marginal effects on financial strain at the most recent available wave

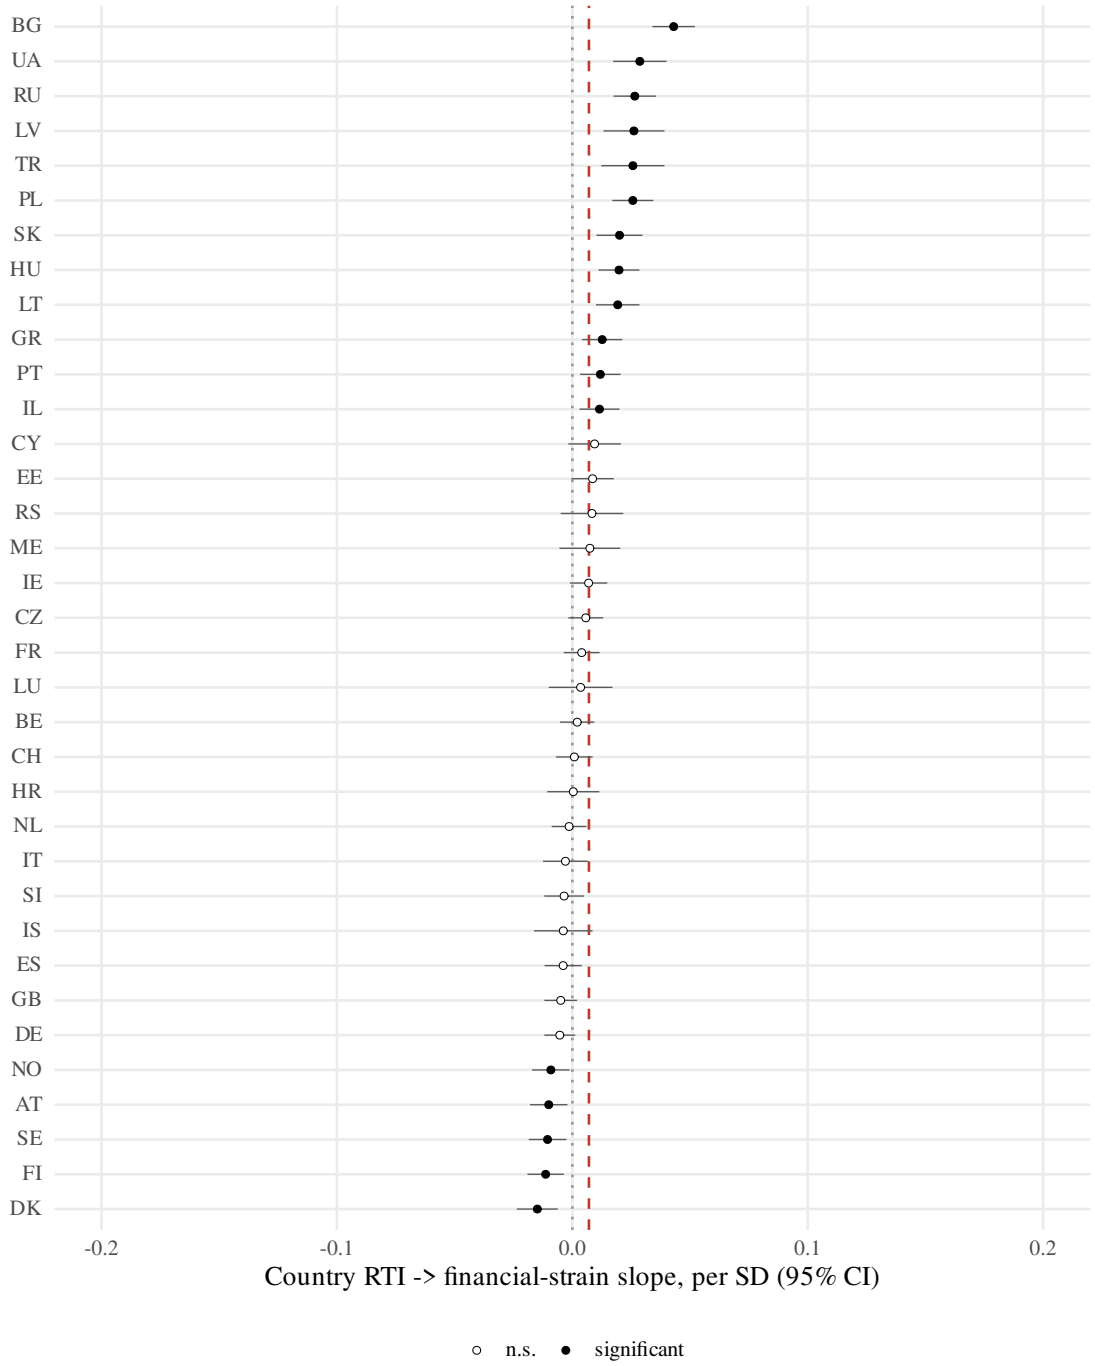

Note: Year in parentheses is each country's most recent ESS round. Whiskers are 95% intervals from the fitted strain slope surface; dotted line at zero. Effect axis fixed at $[-0.20, +0.20]$, shared across all slope figures.

Figure 18: Country heterogeneity in automation exposure and financial strain, Frey–Osborne

Note: Country slopes of the exposure–financial-strain association from the shared model; financial strain is difficulty coping on present income. Dashed red = global slope; dotted line at zero. Effect axis fixed at $[-0.20, +0.20]$, shared across all slope figures.

Figure 19: Country heterogeneity in automation exposure and financial strain, RTI

Note: Country slopes of the exposure–financial-strain association from the shared model; financial strain is difficulty coping on present income. Dashed red = global slope; dotted line at zero. Effect axis fixed at $[-0.20, +0.20]$, shared across all slope figures.

Table 6: Mechanism diagnostic in the welfare-module rounds: automation risk and perceived economic vulnerability

	Job insecurity		Income insufficiency	
Index	2008	2016	2008	2016
Frey–Osborne probability	0.0319***	0.0232***	0.0238***	0.0187***
N	23637	21153	25616	21927
GMS routine-task intensity	0.0190***	0.0090*	0.0110**	0.0016
N	22266	19128	24169	19884

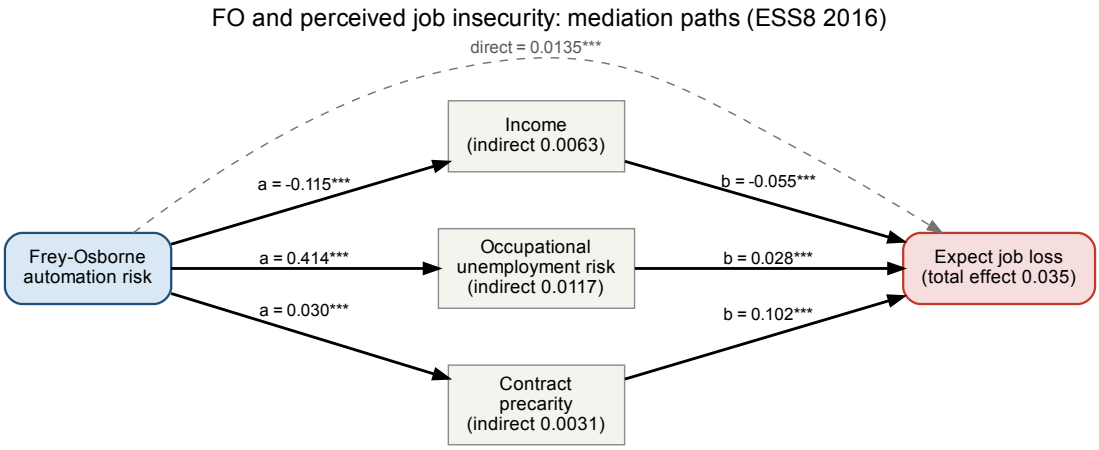

[a] Each cell is the coefficient on the own-occupation automation-risk index in a design-weighted random-intercept linear probability model with country-clustered (CR1) standard errors. The exposure is standardized within the estimation sample, so a coefficient is the change in the probability of feeling vulnerable per one-standard-deviation increase in exposure. "Job insecurity" is a binary indicator for expecting to lose one's job in the next twelve months; "income insufficiency" for expecting income too low to meet needs. The welfare-attitudes module carries both items in the 2008 and 2016 rounds; the job models use the paid-work frame and the income models the labor-force frame. Positive coefficients mean higher exposure predicts greater perceived vulnerability.

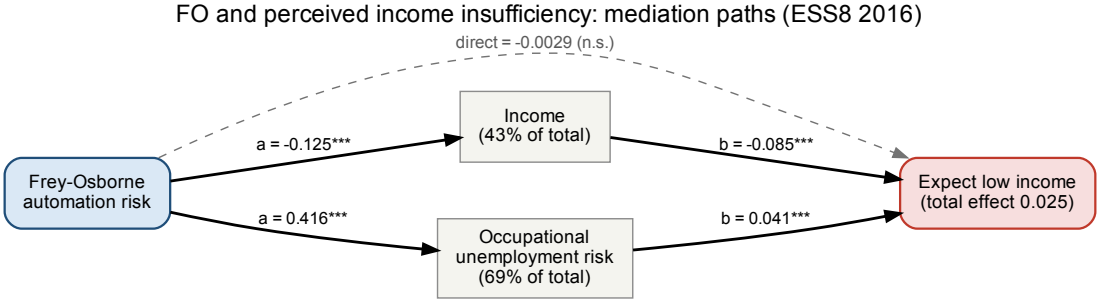

[b] Stars are Holm-adjusted within each outcome-wave across the two indices: * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$. The confirmatory registration covers the 2016 round; the 2008 columns are an out-of-registration extension under the same specification, with occupational exposure taken from the panel's ISCO-88-harmonized indices. Country counts differ across waves and outcomes through module coverage and listwise deletion.

[c] A missing-code recode in the registered pipeline also removed respondents aged 77, 88, and 99; the reported estimates correct this and otherwise preserve the registered specification.

Figure 20: Association decomposition and path diagrams (2016 wave; the expected-job-loss diagram adds contract precarity as a third channel)

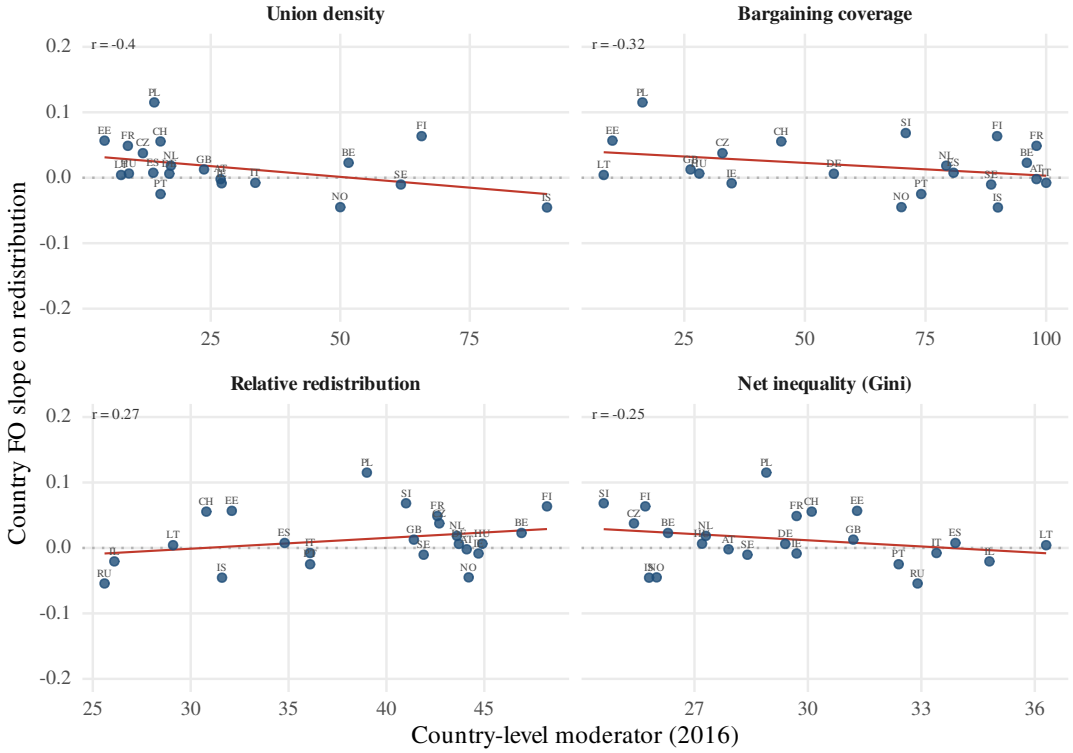

Note: Top: the exposure–vulnerability association decomposed into a direct part (not via measured channels) and indirect parts through each channel (total = direct + channels); colour distinguishes the two outcomes and filled points mark 95% intervals excluding zero. Bottom: the same decomposition as path diagrams, with a and b path coefficients and the implied indirect share per channel. The decomposition is statistical, not causal mediation. The top panel's effect axis is fixed at $[-0.02, +0.05]$, shared across mediation figures.

Figure 21: Two-stage institutional diagnostic for redistribution heterogeneity

Note: Each point is a country at the 2016 wave; β_c is that country's fitted Frey–Osborne slope (per SD) from the single model. Line = OLS across countries; r is shown per panel. Effect axis fixed at $[-0.20, +0.20]$, shared across all slope figures.

Table 7: Between- and within-country institutional moderation of the Frey–Osborne automation–redistribution gradient (Mundlak decomposition)

	Between country		Within country			
Moderator	Est.	(SE)	Est.	(SE)	N	Countries
Net inequality (Gini)	-0.0193	(0.0077)	-0.0070*	(0.0026)	192,956	35
Social spending %GDP	+0.0013	(0.0085)	-0.0131***	(0.0024)	182,856	30
Relative redistribution	+0.0156	(0.0080)	+0.0013	(0.0026)	188,682	32
UB net replacement rate	-0.0092	(0.0074)	+0.0051	(0.0027)	179,834	31
Left cabinet share	-0.0059	(0.0077)	+0.0079**	(0.0023)	178,505	29
Union density	-0.0153	(0.0077)	+0.0152***	(0.0031)	150,193	29
Bargaining coverage	-0.0137	(0.0078)	+0.0151*	(0.0055)	149,939	29
Employment protection (EPL)	+0.0037	(0.0075)	-0.0007	(0.0030)	146,207	25
Industry employment share	+0.0050	(0.0076)	+0.0088**	(0.0025)	178,505	29
Trade openness	+0.0042	(0.0082)	-0.0118**	(0.0033)	160,333	29
Benefit earnings-relatedness	+0.0172	(0.0070)	-0.0048	(0.0025)	179,834	31

Each row is one multilevel model of support for redistribution on standardized Frey–Osborne exposure, following the Mundlak (hybrid) specification: the moderator, lagged one survey year, is split into its country mean (between component) and the deviation from that mean (within component), both standardized, and both interacted with exposure in the same model. Cells report the cross-level interaction coefficients. All models include exposure interactions with contemporaneous unemployment and real GDP growth, the baseline individual controls, year fixed effects, a random exposure slope by country, and a country-year random intercept, with ESS design weights and maximum likelihood estimation. Stars mark Benjamini–Hochberg adjusted p values, corrected across the full family of 44 coefficients (eleven moderators, two components, two exposure indices): * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$.

Table 8: RTI robustness: between- and within-country institutional moderation of the automation–redistribution gradient (Mundlak decomposition)

	Between country		Within country			
Moderator	Est.	(SE)	Est.	(SE)	N	Countries
Net inequality (Gini)	-0.0144	(0.0060)	-0.0042	(0.0026)	178,258	35
Social spending %GDP	+0.0081	(0.0061)	-0.0031	(0.0026)	168,810	30
Relative redistribution	+0.0149	(0.0064)	+0.0001	(0.0026)	174,319	32
UB net replacement rate	+0.0080	(0.0056)	+0.0025	(0.0027)	166,004	31
Left cabinet share	+0.0048	(0.0062)	+0.0035	(0.0024)	164,997	29
Union density	-0.0028	(0.0065)	+0.0119**	(0.0032)	139,220	29
Bargaining coverage	+0.0016	(0.0065)	+0.0141*	(0.0052)	139,038	29
Employment protection (EPL)	-0.0029	(0.0062)	-0.0068	(0.0029)	135,299	25
Industry employment share	+0.0036	(0.0059)	+0.0017	(0.0024)	164,997	29
Trade openness	-0.0011	(0.0069)	-0.0109**	(0.0033)	148,474	29
Benefit earnings-relatedness	+0.0005	(0.0060)	-0.0049	(0.0025)	166,004	31

Each row is one multilevel model of support for redistribution on standardized routine-task-intensity (RTI) exposure, following the Mundlak (hybrid) specification: the moderator, lagged one survey year, is split into its country mean (between component) and the deviation from that mean (within component), both standardized, and both interacted with exposure in the same model. Cells report the cross-level interaction coefficients. All models include exposure interactions with contemporaneous unemployment and real GDP growth, the baseline individual controls, year fixed effects, a random exposure slope by country, and a country-year random intercept, with ESS design weights and maximum likelihood estimation. Stars mark Benjamini–Hochberg adjusted p values, corrected across the full family of 44 coefficients (eleven moderators, two components, two exposure indices): * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$.

8.3 Institutional Moderation: Full Eleven-Moderator Sweep

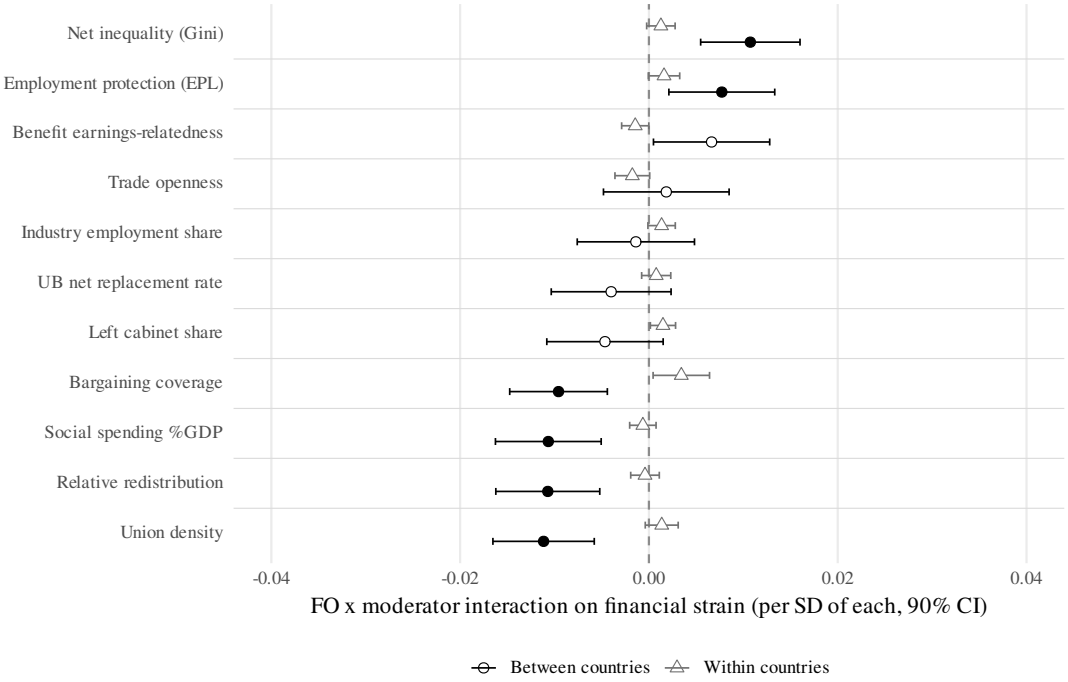

The figures below report the full symmetric sweep of all eleven moderators, each estimated one at a time without institutional controls. The sweep shows every series the focal design classifies, and earlier drafts treated it as primary; it is retained here as robustness for the focal models reported in the body.

Figure 22: Full eleven-moderator sweep, redistribution support

Note: Circles = between-country component (country mean of the lagged moderator); triangles = within-country (deviation from it). Each moderator is estimated one at a time. Filled symbols are significant at Benjamini–Hochberg $q < 0.10$ within the outcome's 44-coefficient family; whiskers are unadjusted 90% CIs, matched to the $q < 0.10$ criterion, so a filled symbol never crosses zero. Effect axis fixed at $[-0.04, +0.04]$, shared across interaction figures.

Figure 23: Full eleven-moderator sweep, financial strain

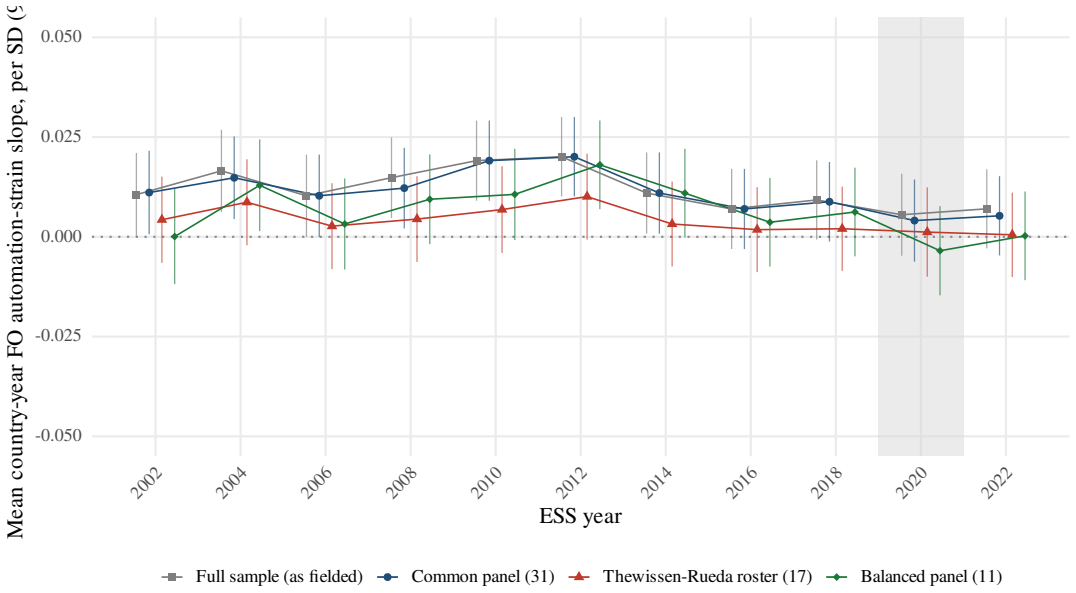

Note: Circles = between-country component (country mean of the lagged moderator); triangles = within-country (deviation from it). Each moderator is estimated one at a time. Filled symbols are significant at Benjamini–Hochberg $q < 0.10$ within the outcome's 44-coefficient family; whiskers are unadjusted 90% CIs, matched to the $q < 0.10$ criterion, so a filled symbol never crosses zero. Effect axis fixed at $[-0.04, +0.04]$, shared across interaction figures.

8.4 Institutional Moderation of the Exposure–Strain Gradient

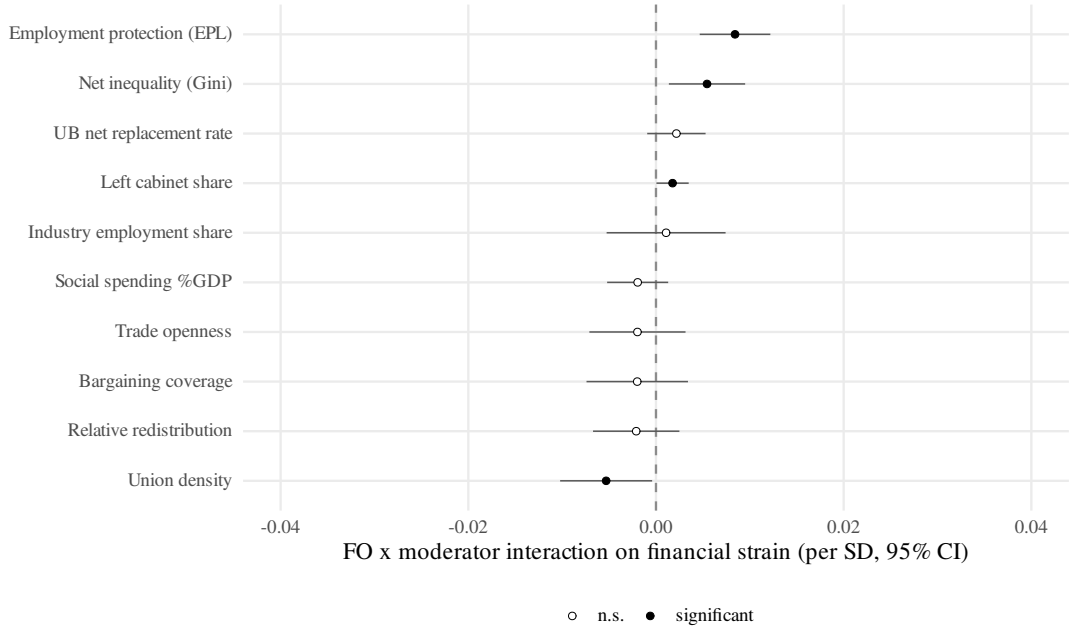

Figure 24 repeats the composition exercise of Figure 3 with financial strain as the outcome, so the mechanism series can be read on the same four country rosters as the redistribution series. The exposure–strain gradient is positive in every wave, significant in six of eleven on the full sample, peaks in 2012, and roughly halves by 2022. All four rosters trace the same path, so the decline is not a product of which countries were fielded. On the Thewissen–Rueda roster the gradient is not distinguishable from zero in any wave, so the mechanism evidence rests on the wider samples.

Figure 24: Yearly Frey–Osborne automation–financial-strain slopes under four composition assumptions

Note: Series are offset horizontally to avoid overlap; the shaded band marks the COVID-disrupted 2020 round (ESS10); dotted line at zero. Whiskers are 95% intervals from the fitted slope surface. Built by the same post-estimation aggregation as Figure 3, applied to the country-year strain slopes. Effect axis fixed at $[-0.05, +0.05]$, shared across mechanism-outcome slope figures. That range is one quarter of the redistribution range, because strain slopes run an order of magnitude smaller; the two figures are therefore not comparable by ink.

Figure 25: Pooled cross-level interactions on financial strain (diagnostic; blends the between- and within-country components)

Note: Points are the pooled cross-level interaction of each lagged moderator with exposure on financial strain, sorted by estimate; filled = 95% interval excludes zero; dashed line at zero. Effect axis fixed at $[-0.04, +0.04]$, shared across interaction figures.

Tables 9 and 10 apply the within–between decomposition of equation 5 to financial strain in place of support for redistribution, holding the specification fixed: the same eleven moderators, the same one-year lag, the same contemporaneous business-cycle adjustment, the same year fixed effects, and the same random exposure slope by country with a country-year random intercept. The outcome is the binary indicator that the household finds it difficult or very difficult to live on its present income, so the models are design-weighted linear probability models and the coefficients are changes in the probability of reported strain per standard deviation of exposure per standard deviation of the moderator component. Individual unemployment is not among the controls, because being unemployed lies on the path from occupational exposure to felt strain. The Benjamini–Hochberg adjustment is applied within this family of forty-four coefficients and is therefore separate from the adjustment reported in Tables 7 and 8. Read together with those tables, the decomposition separates institutional moderation of the first link of the mechanism, from occupational exposure to felt strain, from institutional moderation of the translation of that strain into redistribution demand.

Table 9: Between- and within-country institutional moderation of the Frey–Osborne automation–financial-strain gradient (Mundlak decomposition)

	Between country		Within country			
Moderator	Est.	(SE)	Est.	(SE)	N	Countries
Net inequality (Gini)	+0.0107**	(0.0032)	+0.0013	(0.0009)	193,446	35
Social spending %GDP	-0.0107*	(0.0034)	-0.0006	(0.0008)	183,198	30
Relative redistribution	-0.0107*	(0.0033)	-0.0004	(0.0009)	189,098	32
UB net replacement rate	-0.0040	(0.0039)	+0.0008	(0.0009)	180,173	31
Left cabinet share	-0.0047	(0.0037)	+0.0015	(0.0008)	178,833	29
Union density	-0.0112**	(0.0033)	+0.0014	(0.0011)	150,337	29
Bargaining coverage	-0.0096*	(0.0031)	+0.0034	(0.0018)	150,092	29
Employment protection (EPL)	+0.0077	(0.0034)	+0.0016	(0.0010)	146,298	25
Industry employment share	-0.0014	(0.0038)	+0.0013	(0.0009)	178,833	29
Trade openness	+0.0018	(0.0040)	-0.0018	(0.0011)	160,532	29
Benefit earnings-relatedness	+0.0066	(0.0037)	-0.0015	(0.0009)	180,173	31

Each row is one multilevel model of financial strain, a linear probability model, on standardized Frey–Osborne exposure, following the Mundlak (hybrid) specification: the moderator, lagged one survey year, is split into its country mean (between component) and the deviation from that mean (within component), both standardized, and both interacted with exposure in the same model. Cells report the cross-level interaction coefficients. All models include exposure interactions with contemporaneous unemployment and real GDP growth, the baseline individual controls, year fixed effects, a random exposure slope by country, and a country-year random intercept, with ESS design weights and maximum likelihood estimation. Stars mark Benjamini–Hochberg adjusted p values, corrected across the full family of 44 coefficients (eleven moderators, two components, two exposure indices): $^{*}\,p < 0.05$, $^{**}\,p < 0.01$, $^{***}\,p < 0.001$. Individual unemployment is not among the controls in these models: being unemployed lies on the path from occupational exposure to felt strain, so conditioning on it would block part of the association being measured. The country-level unemployment rate still enters as a level term and as an exposure interaction.

Table 10: RTI robustness: between- and within-country institutional moderation of the automation–financial-strain gradient (Mundlak decomposition)

	Between country		Within country			
Moderator	Est.	(SE)	Est.	(SE)	N	Countries
Net inequality (Gini)	+0.0057*	(0.0022)	+0.0007	(0.0009)	178,695	35
Social spending %GDP	-0.0091***	(0.0019)	+0.0005	(0.0009)	169,103	30
Relative redistribution	-0.0083**	(0.0021)	+0.0003	(0.0009)	174,678	32
UB net replacement rate	-0.0012	(0.0024)	+0.0010	(0.0009)	166,293	31
Left cabinet share	-0.0060*	(0.0023)	-0.0006	(0.0008)	165,278	29
Union density	-0.0069*	(0.0023)	-0.0002	(0.0011)	139,330	29
Bargaining coverage	-0.0084***	(0.0020)	-0.0002	(0.0016)	139,158	29
Employment protection (EPL)	+0.0021	(0.0020)	-0.0002	(0.0010)	135,356	25
Industry employment share	-0.0028	(0.0024)	+0.0008	(0.0008)	165,278	29
Trade openness	+0.0048	(0.0025)	-0.0010	(0.0011)	148,633	29
Benefit earnings-relatedness	+0.0045	(0.0023)	-0.0020	(0.0009)	166,293	31

Each row is one multilevel model of financial strain, a linear probability model, on standardized routine-task-intensity (RTI) exposure, following the Mundlak (hybrid) specification: the moderator, lagged one survey year, is split into its country mean (between component) and the deviation from that mean (within component), both standardized, and both interacted with exposure in the same model. Cells report the cross-level interaction coefficients. All models include exposure interactions with contemporaneous unemployment and real GDP growth, the baseline individual controls, year fixed effects, a random exposure slope by country, and a country-year random intercept, with ESS design weights and maximum likelihood estimation. Stars mark Benjamini–Hochberg adjusted p values, corrected across the full family of 44 coefficients (eleven moderators, two components, two exposure indices): * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$. Individual unemployment is not among the controls in these models: being unemployed lies on the path from occupational exposure to felt strain, so conditioning on it would block part of the association being measured. The country-level unemployment rate still enters as a level term and as an exposure interaction.

8.5 NACE Rev. 2.1: First-Level Economic-Activity Classification

Table 11: Statistical Classification of Economic Activities in the European Community, Rev. 2.1 (NACE Rev. 2.1)

Section	Code Range	Description
A	01:03	Agriculture, Forestry and Fishing
B	05:09	Mining and Quarrying
C	10:33	Manufacturing
D	35:35	Electricity, Gas, Steam and Air Conditioning Supply
E	36:39	Water Supply; Sewerage, Waste Management and Remediation Activities
F	41:43	Construction
G	45:47	Wholesale and Retail Trade
H	49:53	Transportation and Storage
I	55:56	Accommodation and Food Service Activities
J	58:60	Publishing, Broadcasting, and Content Production and Distribution Activities
K	61:63	Telecommunication, Computer Programming, Consulting, Computing Infrastructure and Other Information Service Activities
L	64:66	Financial and Insurance Activities
M	68:68	Real Estate Activities
N	69:75	Professional, Scientific and Technical Activities
O	77:82	Administrative and Support Service Activities
P	84:84	Public Administration and Defence; Compulsory Social Security
Q	85:85	Education
R	86:88	Human Health and Social Work Activities
S	90:93	Arts, Sports and Recreation
T	94:96	Other Service Activities
U	97:98	Activities of Households as Employers and Undifferentiated Goods - and Service-Producing Activities of Households for Own Use
V	99:99	Activities of Extraterritorial Organisations and Bodies

8.6 Standard Occupational Classification (SOC) System

The 2010 Standard Occupational Classification (SOC-2010) is the U.S. statistical system for classifying occupations, which federal agencies use to organize occupational information and labor-market data.

SOC-2010 is hierarchical, ranging from broad groups down to more than 800 specific occupations identified by unique codes.

Major Categories of SOC-2010

The table below lists the SOC-2010 major groups.

Table 12: Major Categories of SOC-2010

Code	Major Group	Code	Major Group
11	Management Occupations	33	Protective Service Occupations
13	Business and Financial Operations Occupations	35	Food Preparation and Serving Related Occupations
15	Computer and Mathematical Occupations	37	Building and Grounds Cleaning and Maintenance Occupations
17	Architecture and Engineering Occupations	39	Personal Care and Service Occupations
19	Life, Physical, and Social Science Occupations	41	Sales and Related Occupations
21	Community and Social Service Occupations	43	Office and Administrative Support Occupations
23	Legal Occupations	45	Farming, Fishing, and Forestry Occupations
25	Education, Training, and Library Occupations	47	Construction and Extraction Occupations
27	Arts, Design, Entertainment, Sports, and Media Occupations	49	Installation, Maintenance, and Repair Occupations
29	Healthcare Practitioners and Technical Occupations	51	Production Occupations
31	Healthcare Support Occupations	53	Transportation and Material Moving Occupations

8.7 Descriptive Statistics

Table 13: Descriptive statistics for the analysis variables of the harmonised 2002–2022 labour-force panel (all eleven ESS waves). Each row is a model variable; the columns report the number of non-missing observations (N), the mean and standard deviation, and the minimum, the tenth, twenty-fifth, fiftieth, seventy-fifth, and ninetieth percentiles, and the maximum. Binary indicators have means equal to their prevalence in the sample. The Frey–Osborne automation probability is on its native 0–1 scale, the routine-task-intensity index on its native GMS scale, and relative equivalized income enters as the within-country-year z-score. The vulnerability items exist only in the waves noted.

Variable	N	Mean	SD	Min	p10	p25	Median	p75	p90	Max
Redistribution support (1–5) (`y`)	268,926	3.84	1.05	1.00	2.00	3.00	4.00	5.00	5.00	5.00
Frey–Osborne automation probability (`fo`)	254,651	0.51	0.34	0.00	0.04	0.13	0.57	0.81	0.95	0.99
Routine-task intensity (GMS) (`rti`)	235,429	-0.14	0.95	-1.52	-1.00	-0.73	-0.44	0.32	1.41	2.24
Relative equivalized income (z) (`income`)	212,990	0.21	1.06	-21.31	-0.79	-0.45	-0.02	0.60	1.54	24.39
Years of education (`eduyrs`)	269,968	13.61	3.75	0.00	9.00	12.00	13.00	16.00	18.00	56.00
Age (`age`)	271,056	42.76	12.27	14.00	26.00	33.00	43.00	52.00	59.00	114.00
Male (`male`)	272,204	0.52	0.50	0.00	0.00	0.00	1.00	1.00	1.00	1.00
Union member (current/former) (`union`)	269,865	0.41	0.49	0.00	0.00	0.00	0.00	1.00	1.00	1.00
Religiosity (0–10) (`relig`)	269,892	4.32	2.98	0.00	0.00	2.00	5.00	7.00	8.00	10.00
Unemployed (active) (`unemp`)	272,328	0.07	0.26	0.00	0.00	0.00	0.00	0.00	0.00	1.00
Financial strain (difficult on income) (`d_fin_strain`)	268,316	0.22	0.41	0.00	0.00	0.00	0.00	0.00	1.00	1.00
Expects job loss (2008, 2016) (`d_job_vulnr`)	50,795	0.26	0.44	0.00	0.00	0.00	0.00	1.00	1.00	1.00
Expects insufficient income (2008, 2016) (`d_income_vulnr`)	50,617	0.28	0.45	0.00	0.00	0.00	0.00	1.00	1.00	1.00
Job not secure (2004, 2010) (`d_job_insecure`)	37,982	0.36	0.48	0.00	0.00	0.00	0.00	1.00	1.00	1.00
Occupational unemployment risk (`occ_risk`)	263,975	0.06	0.05	0.00	0.02	0.03	0.05	0.08	0.12	1.00
Temporary or no contract (`no_or_limtd_contract`)	212,928	0.21	0.41	0.00	0.00	0.00	0.00	0.00	1.00	1.00

8.8 ESS Variable Dictionary

Table 14: ESS variable dictionary

Variable	Description	Value labels
`y`	Redistribution preference; the ESS item gincdif reverse-coded (y = 6 - gincdif) so higher values mean stronger support for the government reducing income differences.	'5' = 'Agree strongly'; '4' = 'Agree'; '3' = 'Neither agree nor disagree'; '2' = 'Disagree'; '1' = 'Disagree strongly'
`fo`	Frey-Osborne (2017) probability that the respondent's occupation is automatable, matched to the occupation code and harmonized across the ISCO-88 and ISCO-08 waves.	Continuous, 0 to 1
`rti`	Goos-Manning-Salomons routine-task-intensity of the occupation (appendix robustness exposure), harmonized across the ISCO seam.	Continuous; higher is more routine-task-intensive
`income`	Thewissen-Rueda relative equivalized household income, entered as the within country-year z-score. Built from the ESS show-card income band midpoint (Pareto mean for the open top band), square-root household equivalization, and the ratio to the design-weighted country-year mean.	Continuous z-score
`eduyrs`	Years of full-time education completed (ESS eduyrs).	Continuous, years
`male`	Respondent gender, from ESS gndr.	'1' = 'Male'; '0' = 'Female'
`age`	Age of the respondent in years (ESS agea).	Continuous, years
`union`	Trade-union membership, from ESS mbtru.	'1' = 'Member, current or former'; '0' = 'Never a member'
`relig`	Subjective religiosity on the ESS rlgdgr scale.	'0' = 'Not at all religious'; '10' = 'Very religious'
`unemp`	Unemployed under the Thewissen-Rueda labour-force definition (ESS mnactic coded as unemployed, looking or not looking for work).	'1' = 'Unemployed'; '0' = 'Employed'

Continued on next page

Variable	Description	Value labels
occ_risk	Occupational unemployment risk, Rehm-style: the design-weighted, leave-one-out unemployment rate by wave and two-digit ISCO under the ILO labour-force definition (minimum cell size of 30).	Continuous, share unemployed
no_or_limtd_contract	Contract precarity, from ESS wrkctra.	'1' = 'Limited-duration or no contract'; '0' = 'Unlimited contract'
d_fin_strain	Subjective financial strain, from ESS hincfel; available in all eleven waves.	'1' = 'Difficult or very difficult on present income'; '0' = 'Coping or living comfortably'
d_job_vulnr	Expected job loss, from ESS lkuemp (likely or very likely to become unemployed in the next twelve months). Welfare module, 2008 and 2016.	'1' = 'Likely or very likely'; '0' = 'Not or not very likely'
d_income_vulnr	Expected income insufficiency, from ESS lknemny (likely or very likely to have insufficient household income in the next twelve months). Welfare module, 2008 and 2016.	'1' = 'Likely or very likely'; '0' = 'Not or not very likely'
d_job_insecure	Job insecurity, from ESS jbscr (rates own job security low). Work module, 2004 and 2010.	'1' = 'Insecure'; '0' = 'Secure'
dweight	ESS design weight, applied in all estimation.	Continuous weight
country	ESS country of interview (39 countries, ISO codes).	Categorical
year	ESS survey year and wave, 2002 to 2022 (rounds 1 to 11).	Categorical, 2002 to 2022

8.9 Institutional Measures Dictionary

Table 15 defines each institutional moderator and records its source series and country coverage.

Table 15: Institutional moderators: definitions and sources

Variable	Measure	Description	Source	Ctries
gininet	Net inequality (Gini)	Gini index of net (post-tax, post-transfer) income inequality, in Gini points.	SWIID, version 9.92	35
relred	Relative redistribution	Reduction of market-income inequality achieved by taxes and transfers, as recorded in the SWIID relative-redistribution series (percent).	SWIID, version 9.92	32
socgdp	Social spending %GDP	Public social expenditure as a share of GDP (percent).	OECD SOCX	30
nrr_m6	UB net replacement rate	Net unemployment-benefit replacement rate for a single person without children at 67% of the average wage, six months into unemployment, without social-assistance top-ups (percent).	OECD tax-benefit models	31
nrr_decay_m6	Benefit earnings-relatedness	Decay of the net replacement rate as previous earnings rise: NRR at 100% of the average wage minus NRR at 67%, six months into unemployment (percentage points). Values near zero indicate earnings-related benefits; strongly negative values indicate flat or capped benefits.	OECD tax-benefit models	31
ud_ipol	Union density	Union density, interpolated from the OECD/AIAS ICTWSS series (percent of employees).	CPDS (OECD/AIAS ICTWSS)	29
adjcov_ipol	Bargaining coverage	Adjusted collective-bargaining coverage, interpolated from the OECD/AIAS ICTWSS series (percent of employees).	CPDS (OECD/AIAS ICTWSS)	29
emprot_reg	Employment protection (EPL)	Strictness of employment protection for regular contracts (index), per the CPDS series emprot_reg.	CPDS	25
gov_left1	Left cabinet share	Share of cabinet posts held by left parties (percent), per the CPDS series gov_left1.	CPDS	29
emp_ind	Industry employment share	Employment in industry, per the CPDS series emp_ind.	CPDS	29
openc	Trade openness	Trade openness: exports plus imports as a share of GDP (percent), per the CPDS series openc.	CPDS	29

Ctries: national clusters available to the moderation models, from the estimation output. Moderators enter the models standardized and lagged one survey year. CPDS: Comparative Political Data Set (Armingeon et al., 2025). SWIID: Standardized World Income Inequality Database.

8.10 Alternative Explanations and Individual-Level Correlations

Table 16 refits the baseline gradient model adding one rival explanation at a time, following the architecture of Thewissen and Rueda (2019). Rivals also enter simultaneously in the final row because no pairwise correlation among them exceeds $|0.5|$ and no variance-inflation factor exceeds 5. When either bound is crossed, the design reverts to one at a time. Table 17 reports the individual-level correlations behind that rule. The occupation-dummy row changes the estimand rather than adding a rival: exposure is an occupation-level score, so once one-digit groups are absorbed the coefficient is identified from residual variation across detailed occupations within them, and there it turns negative. The gradient the paper studies is carried by differences between major occupational groups.

Table 16: The exposure gradient under one rival explanation at a time

	Frey–Osborne		RTI	
Added rival	Exposure coef.	(SE)	Exposure coef.	(SE)
Baseline (none)	0.025	(0.008)	0.014	(0.006)
Left-right self-placement	0.027	(0.007)	0.014	(0.006)
Occupational unemployment risk	0.006	(0.008)	0.002	(0.006)
Temporary or no contract	0.025	(0.008)	0.014	(0.006)
Household size	0.025	(0.008)	0.013	(0.006)
One-digit occupation dummies	-0.022	(0.008)	-0.013	(0.008)
All rivals simultaneously	0.010	(0.007)	0.004	(0.006)

Each row refits the baseline gradient model with one rival added; the coefficient shown is on standardized exposure. Common complete-case sample per index ($N = 142,833$ FO, $N = 132,037$ RTI), year fixed effects, random exposure slope by country, country-year intercept. Rivals enter together in the final row only because no rival pairwise correlation exceeds $|0.5|$ and no variance-inflation factor exceeds 5; occupation dummies stay one at a time because exposure is an occupation-level score, so they change the estimand to within-occupation.

Table 17: Individual-level correlations of exposure and the rival explanations

	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)
(1) FO exposure									
(2) RTI exposure	0.59								
(3) Left-right (0-10)	0.01	-0.02							
(4) Relative income	-0.21	-0.13	0.06						
(5) Education (years)	-0.37	-0.16	-0.03	0.26					
(6) Occ. unemployment risk	0.48	0.26	-0.01	-0.22	-0.34				
(7) Temporary/no contract	0.07	0.02	-0.02	-0.13	-0.07	0.15			
(8) Financial strain	0.15	0.07	-0.02	-0.27	-0.19	0.21	0.13		
(9) Redistribution support	0.10	0.07	-0.19	-0.15	-0.12	0.11	0.05	0.15	

Pairwise complete observations on the harmonized panel; lower triangle shown.

8.11 Full Regression Tables

The tables in this section report every estimated coefficient for each specification in the paper, including the individual-level control vector, the business-cycle terms, the random-effects standard deviations, and the sample sizes. Models appear as columns within a specification family. Year dummies are estimated in every multilevel model and are indicated by a row rather than printed, and continuous moderators and exposure indices are standardized, so coefficients are per standard deviation.

Coefficients with standard errors in parentheses. $^{*}p < 0.05$, $^{**}p < 0.01$, $^{***}p < 0.001$, from the normal approximation for the multilevel fits; these are unadjusted p-values, and the Benjamini–Hochberg adjustment reported in the body tables applies to the focal interactions only. Exposure and all continuous moderators are standardised. Year dummies are estimated but not printed. Random-effects rows are standard deviations.
